COURSE PLAN – PART II

COURSE OVERVIEW

A compiler is a system software that translates the code written in one language to some other language without altering the meaning of the program. A compiler should also produce the target code which is efficient and optimized. Compiler design principles provide an in-depth view of translation from a source (high-level) language to target (low-level typically assembly) language followed by optimization. The compiler involves six phases namely, lexical, syntax, semantic analysis as front end, and intermediate code generation, code generation and optimization as back-end. This course discusses these six phases of the compiler in detail by providing appropriate algorithms, methodologies and its implementation at all phases.
